1. Ensure that the thermoformer is unplugged and completely cooled before proceeding.

2. Inspect the plug and confirm the wires are properly connected. The outer black shielding cable should be secured inside the yellow plug. Loosen the screws on the outside of the plug and slide the cover back to allow visual inspection of each wire connection. Verify that there are no burn marks or loose wires.

3. Inspect the junction box located on the underside of the thermoformer. Loosen the screw, remove cover plate and confirm all wires are secured.

4. Inspect the element connections by removing the two screws on either end of the thermoformer and by removing the aluminum angle. Carefully slide the fire brick outwards, making sure the wiring remains connected. Verify that there are no burn marks.

If you have further questions please contact your local Technical Services Representative.
